

Chapter 12 Exception Handling and Text IO

Motivations

When a program runs into a runtime error, the program terminates abnormally. How can you handle the runtime error so that the program can continue to run or terminate gracefully? This is the subject we will introduce in this chapter.

Objectives

- ★ To get an overview of exceptions and exception handling (§12.2).
- ▯ To explore the advantages of using exception handling (§12.2).
- ▯ To distinguish exception types: **Error** (fatal) vs. **Exception** (nonfatal) and checked vs. unchecked (§12.3).
- ▯ To declare exceptions in a method header (§12.4.1).
- ▯ To throw exceptions in a method (§12.4.2).
- ▯ To write a **try-catch** block to handle exceptions (§12.4.3).
- ▯ To explain how an exception is propagated (§12.4.3).
- ▯ To obtain information from an exception object (§12.4.4).
- ▯ To develop applications with exception handling (§12.4.5).
- ▯ To use the **finally** clause in a **try-catch** block (§12.5).
- ▯ To use exceptions only for unexpected errors (§12.6).
- ▯ To rethrow exceptions in a **catch** block (§12.7).
- ▯ To create chained exceptions (§12.8).
- ▯ To define custom exception classes (§12.9).
- ▯ To discover file/directory properties, to delete and rename files/directories, and to create directories using the **File** class (§12.10).
- ▯ To write data to a file using the **PrintWriter** class (§12.11.1).
- ▯ To use try-with-resources to ensure that the resources are closed automatically (§12.11.2).
- ▯ To read data from a file using the **Scanner** class (§12.11.3).
- ▯ To understand how data is read using a **Scanner** (§12.11.4).
- ▯ To develop a program that replaces text in a file (§12.11.5).
- ▯ To read data from the Web (§12.12).
- ▯ To develop a Web crawler (§12.13).

Exception-Handling Overview

Show runtime error

Quotient

Fix it using an if statement

QuotientWithIf

With a method

QuotientWithMethod

Exception Advantages

QuotientWithException

Now you see the *advantages* of using exception handling. It enables a method to throw an exception to its caller. Without this capability, a method must handle the exception or terminate the program.

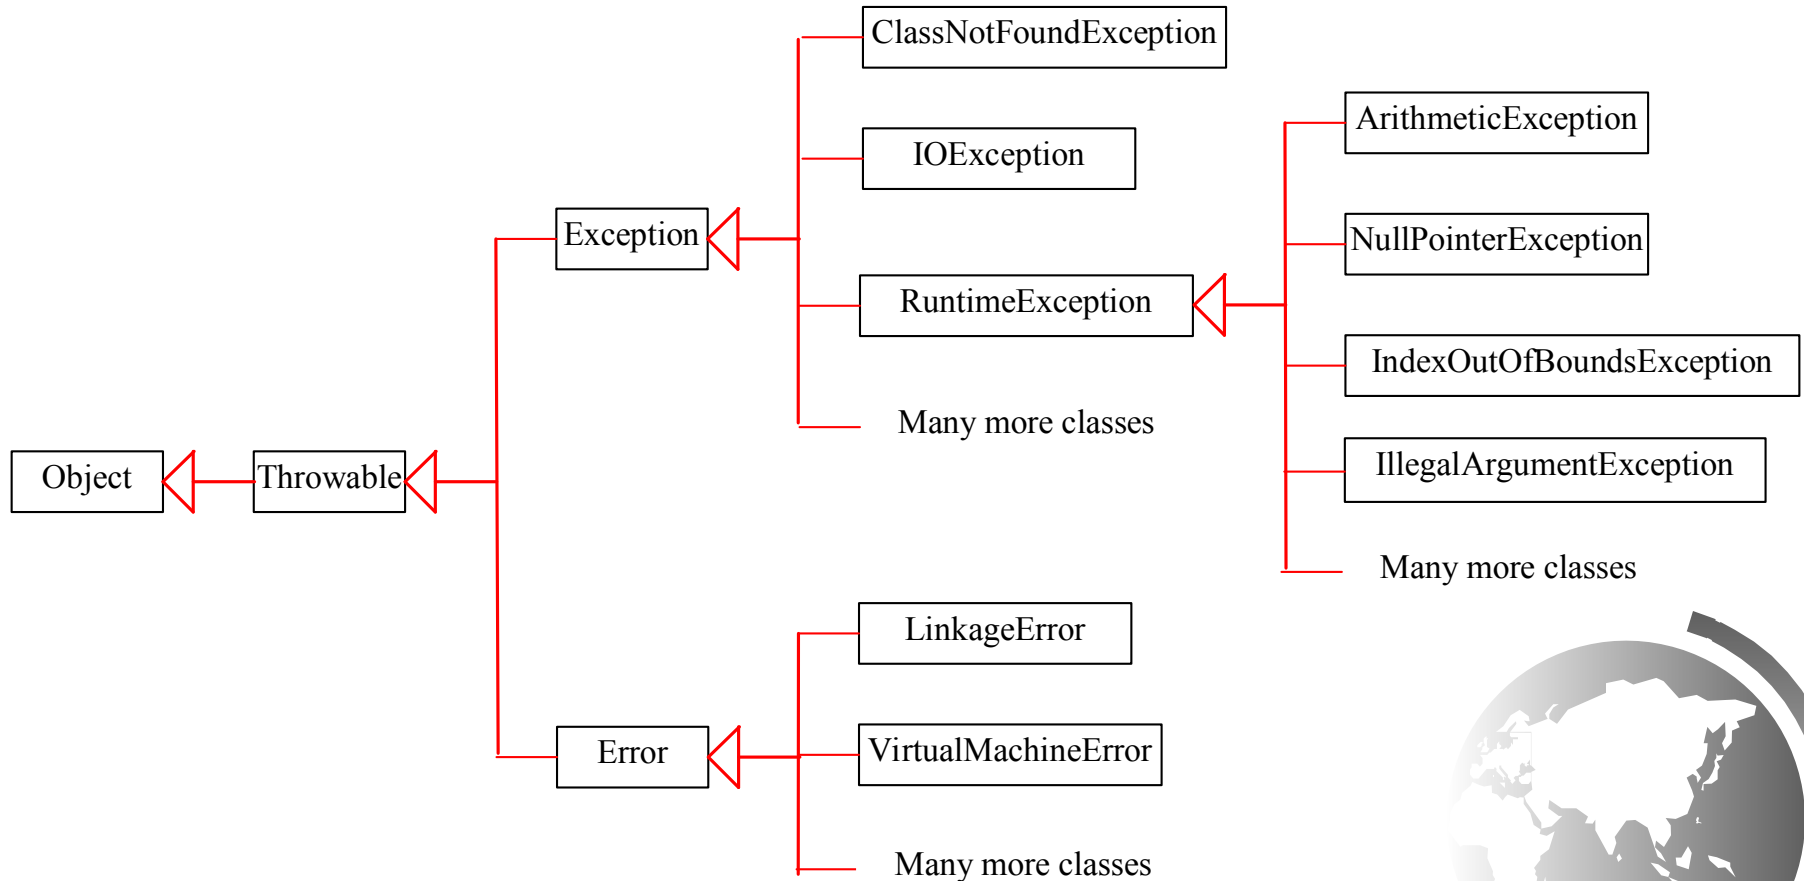

Handling InputMismatchException

InputMismatchExceptionDemo

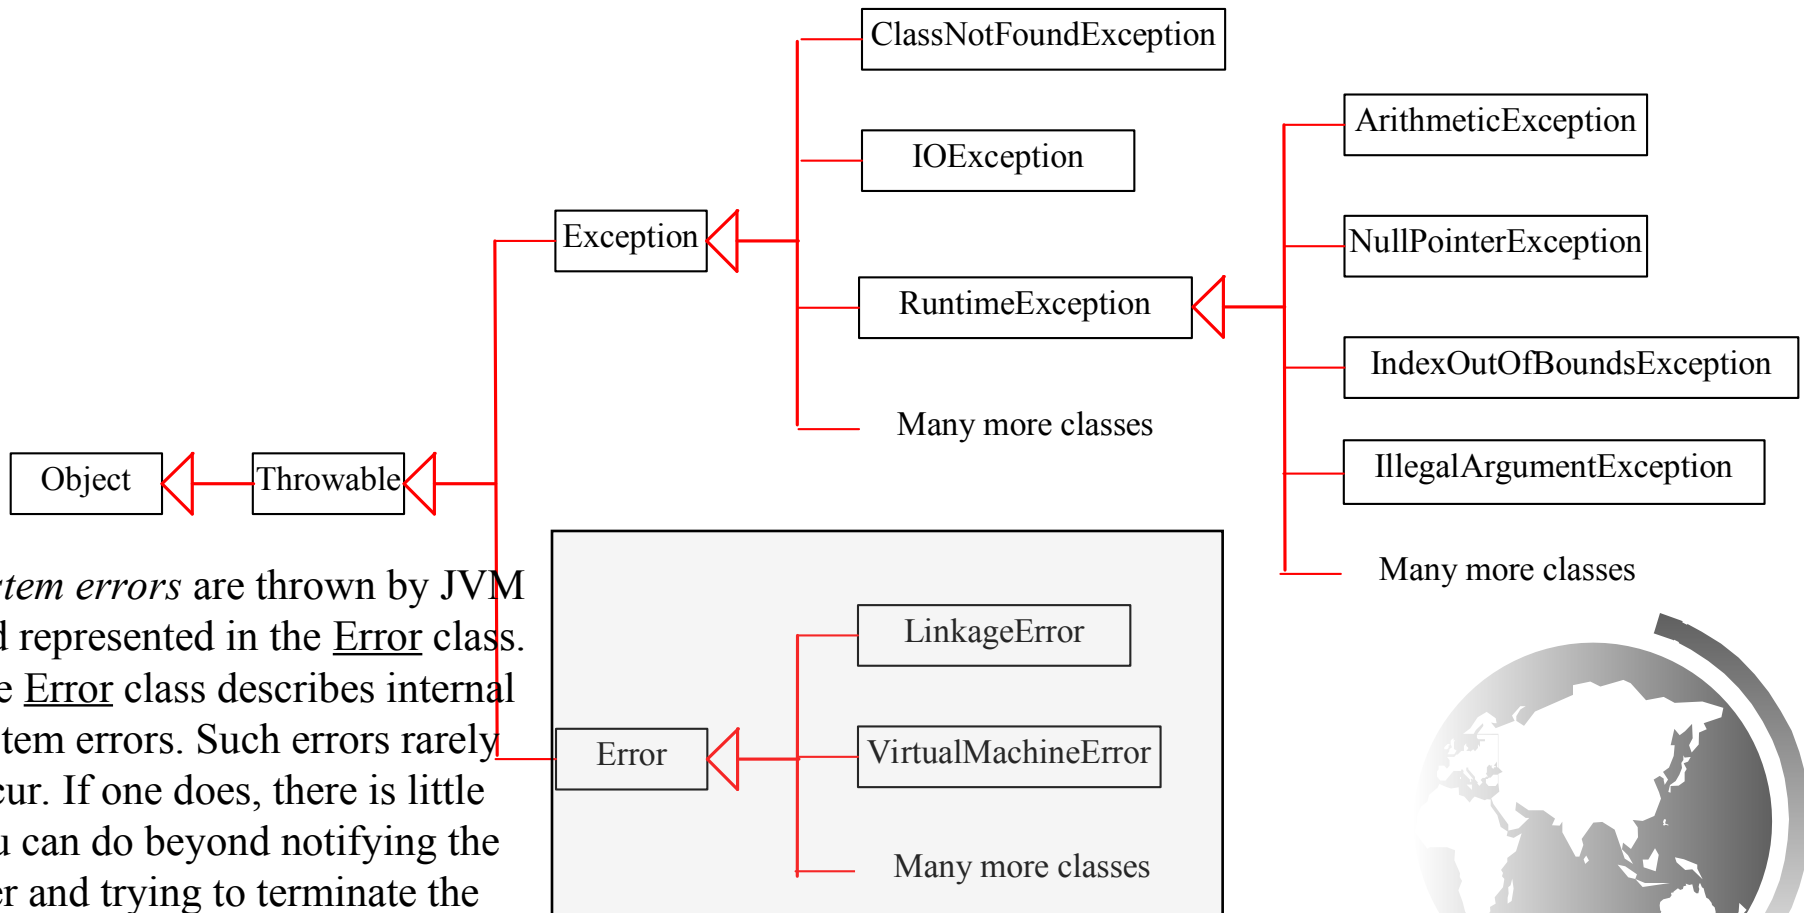

By handling InputMismatchException, your program will continuously read an input until it is correct.

Exception Types

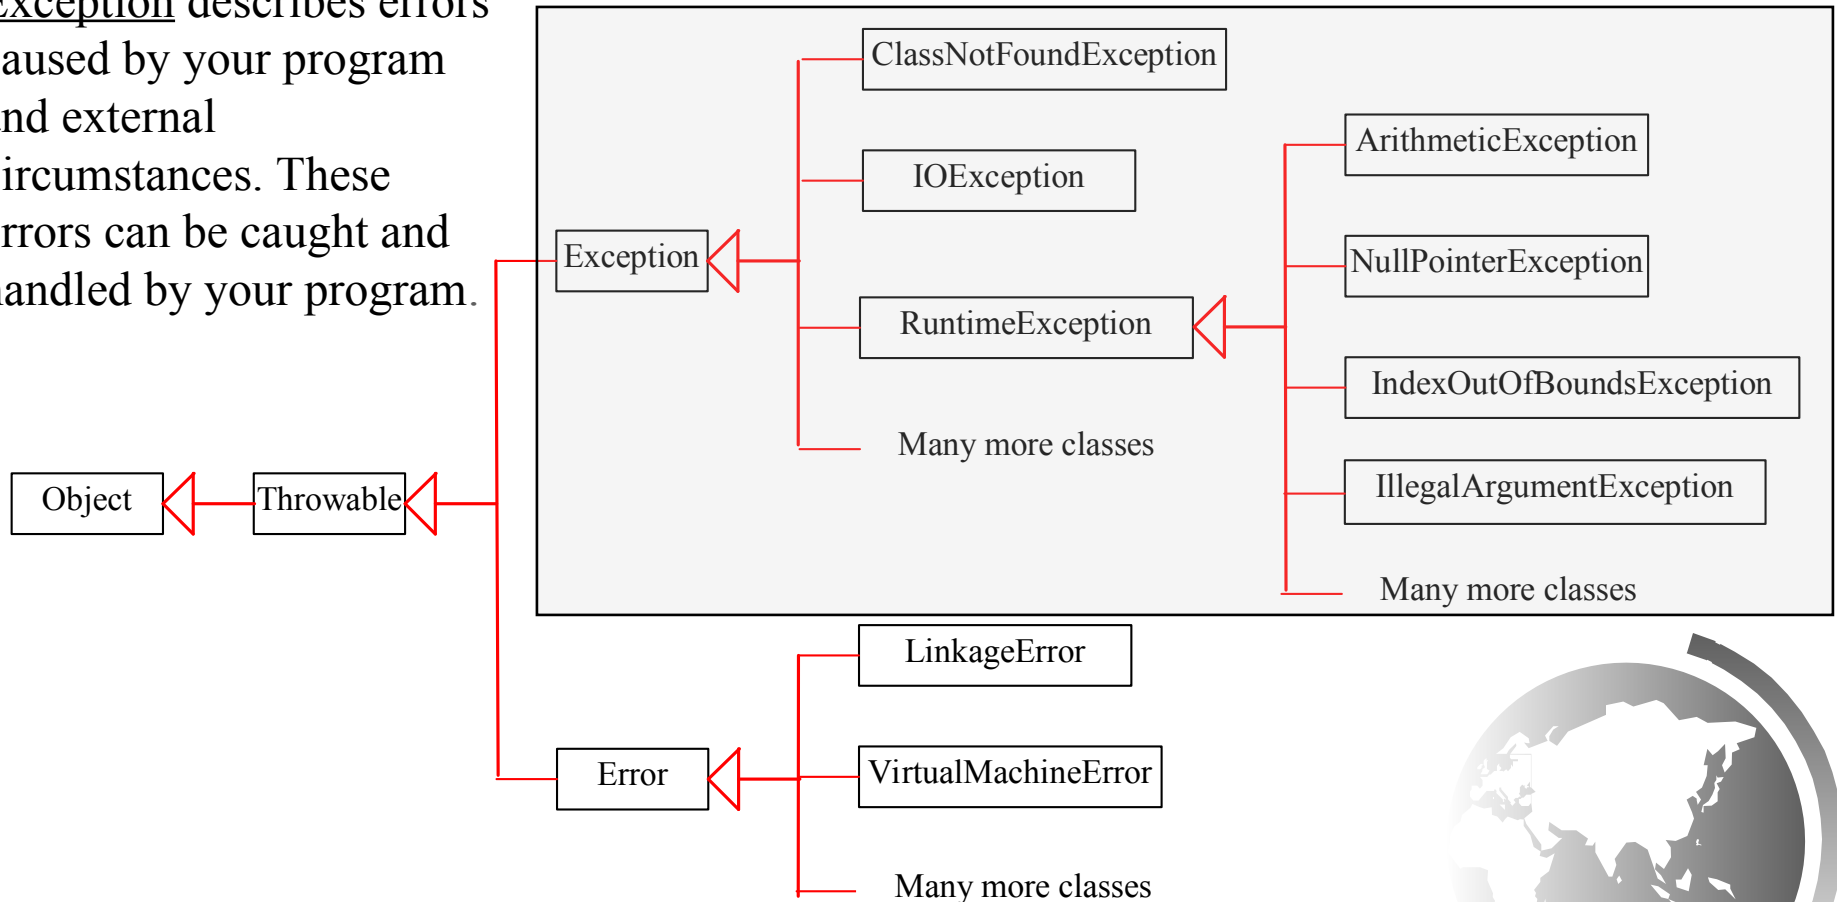

System Errors

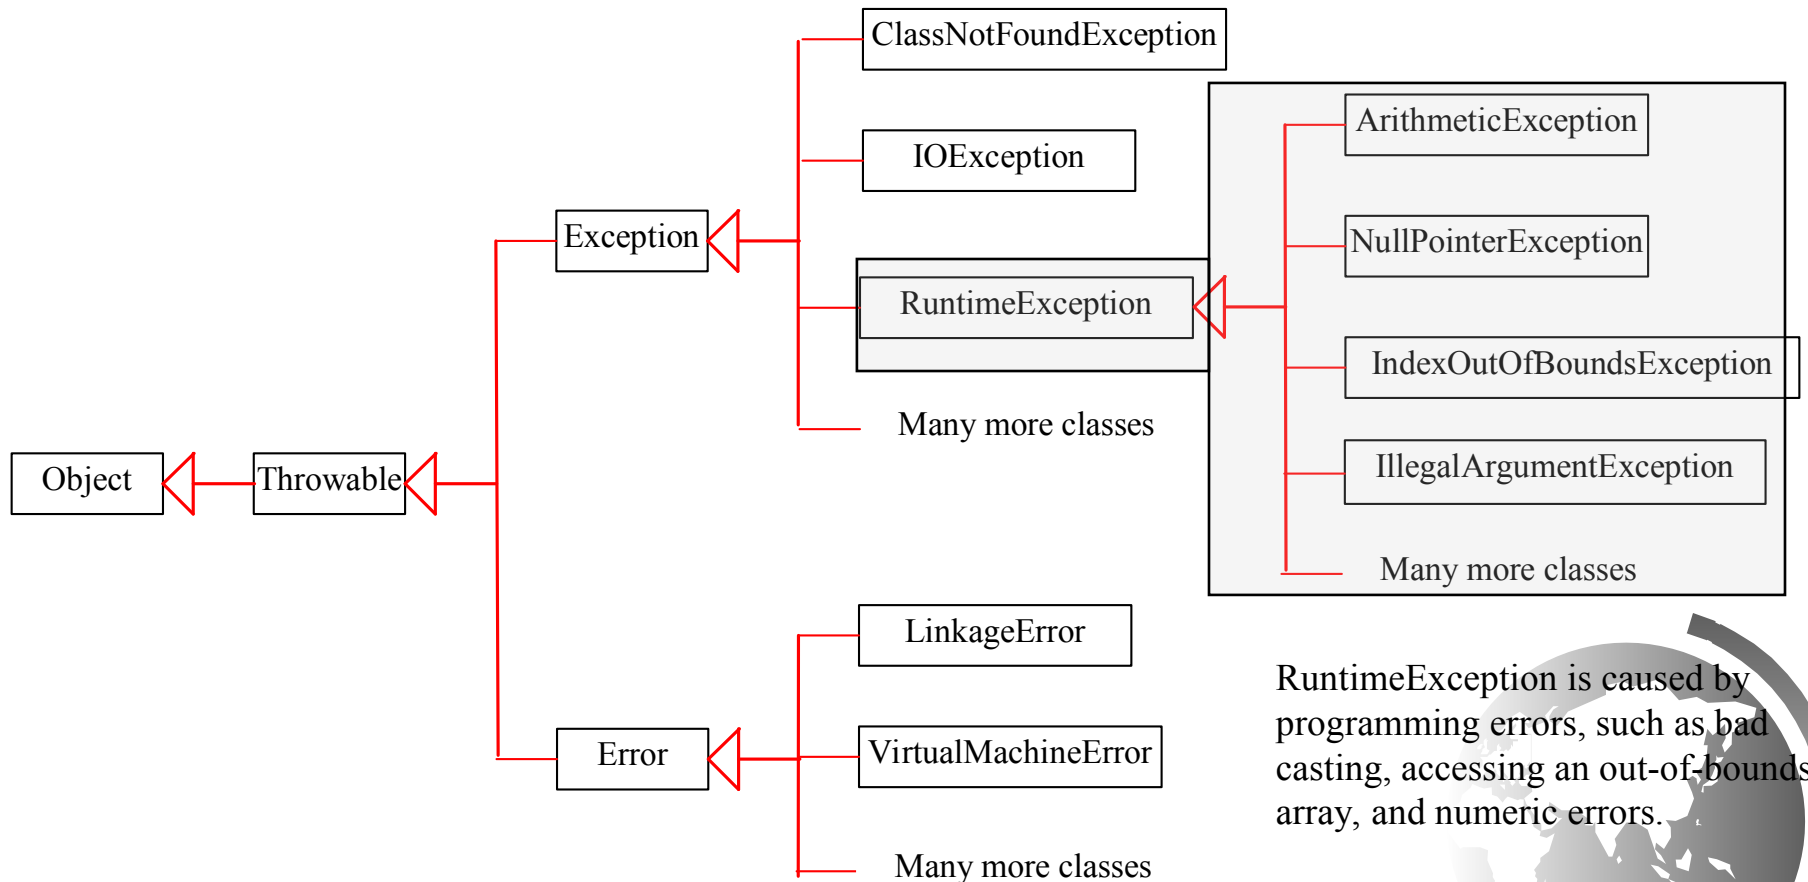

Exceptions

Exception describes errors caused by your program and external circumstances. These errors can be caught and handled by your program.

Runtime Exceptions

RuntimeException is caused by programming errors, such as bad casting, accessing an out-of-bounds array, and numeric errors.

Checked Exceptions vs. Unchecked Exceptions

RuntimeException, Error and their subclasses are known as *unchecked exceptions*. All other exceptions are known as *checked exceptions*, meaning that the compiler forces the programmer to check and deal with the exceptions.

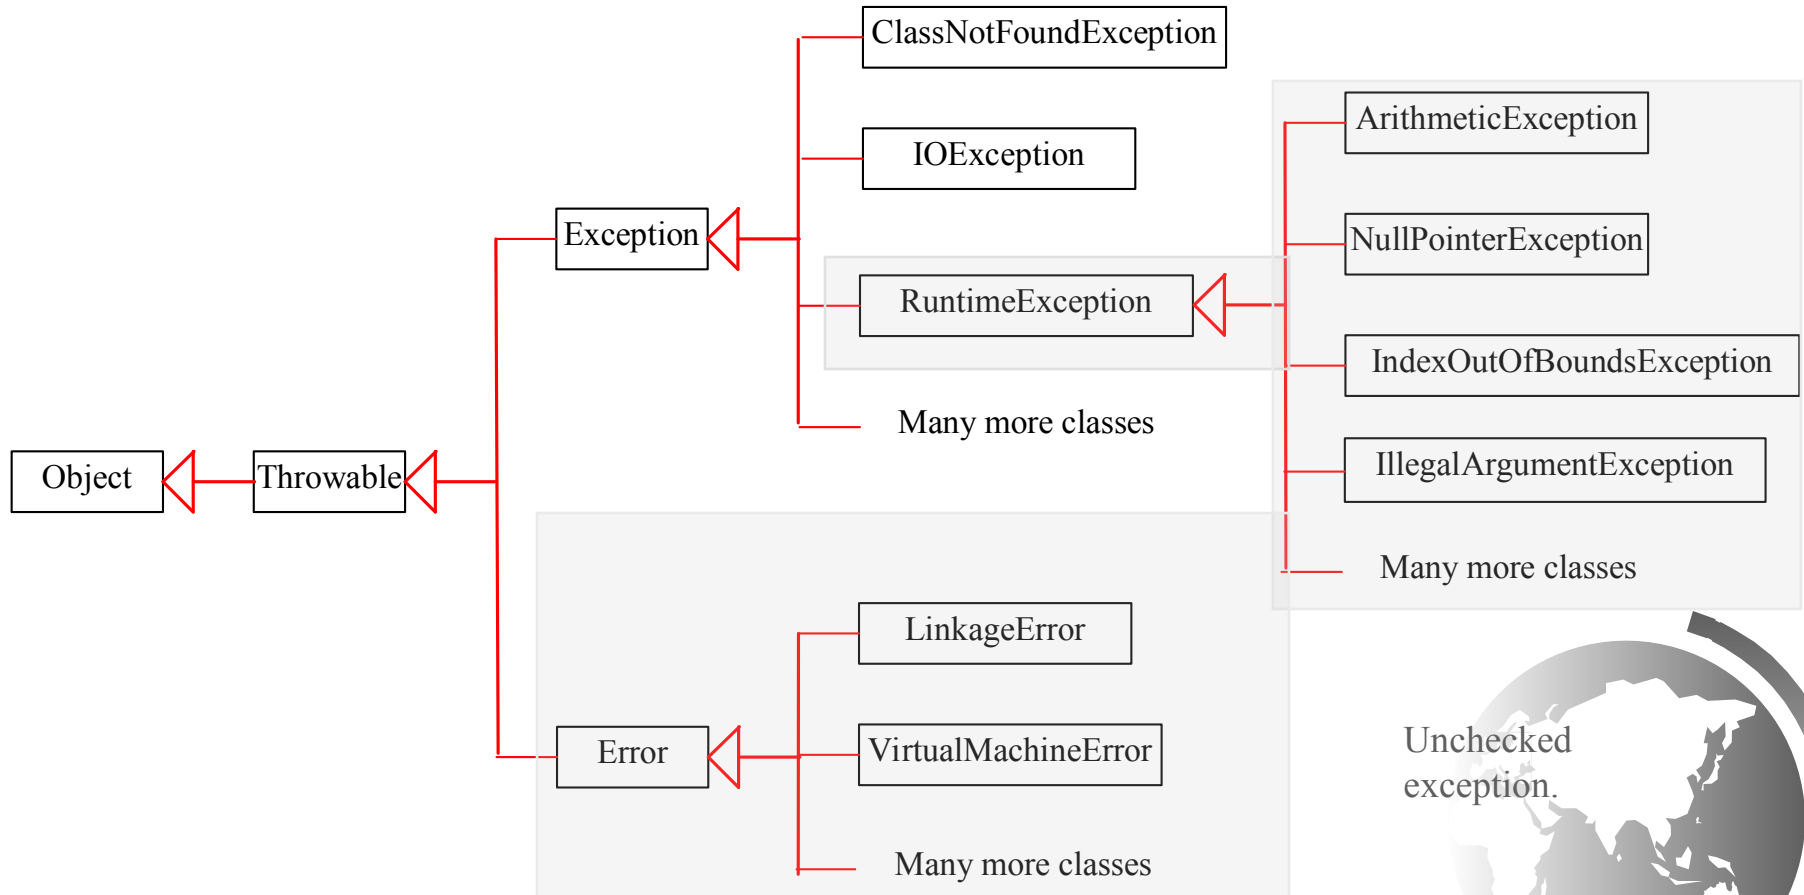

Unchecked Exceptions

In most cases, unchecked exceptions reflect programming logic errors that are not recoverable. For example, a `NullPointerException` is thrown if you access an object through a reference variable before an object is assigned to it; an `IndexOutOfBoundsException` is thrown if you access an element in an array outside the bounds of the array.

These are the logic errors that should be corrected in the program. Unchecked exceptions can occur anywhere in the program. To avoid cumbersome overuse of try-catch blocks, Java does not mandate you to write code to catch unchecked exceptions.

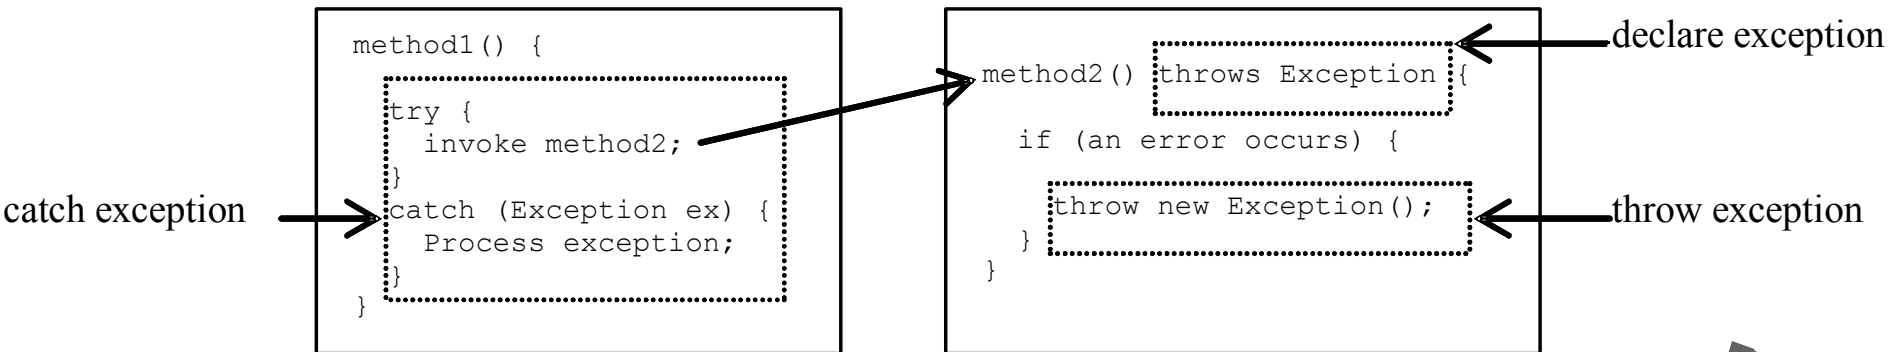

Unchecked Exceptions

Unchecked
exception.

Declaring, Throwing, and Catching Exceptions

Declaring Exceptions

Every method must state the types of checked exceptions it might throw. This is known as *declaring exceptions*.

```
public void myMethod()  
    throws IOException
```

```
public void myMethod()  
    throws IOException, OtherException
```

Throwing Exceptions

When the program detects an error, the program can create an instance of an appropriate exception type and throw it. This is known as *throwing an exception*. Here is an example,

```
throw new TheException();
```

```
TheException ex = new TheException();  
throw ex;
```

Throwing Exceptions Example

```
/** Set a new radius */  
public void setRadius(double newRadius)  
    throws IllegalArgumentException {  
    if (newRadius >= 0)  
        radius = newRadius;  
    else  
        throw new IllegalArgumentException(  
            "Radius cannot be negative");  
}
```

Catching Exceptions

```
try {  
    statements; // Statements that may throw exceptions  
}  
catch (Exception1 exVar1) {  
    handler for exception1;  
}  
catch (Exception2 exVar2) {  
    handler for exception2;  
}  
...  
catch (ExceptionN exVar3) {  
    handler for exceptionN;  
}
```

Catching Exceptions

```
main method {  
    ...  
    try {  
        ...  
        invoke method1;  
        statement1;  
    }  
    catch (Exception1 ex1) {  
        Process ex1;  
    }  
    statement2;  
}
```

```
method1 {  
    ...  
    try {  
        ...  
        invoke method2;  
        statement3;  
    }  
    catch (Exception2 ex2) {  
        Process ex2;  
    }  
    statement4;  
}
```

```
method2 {  
    ...  
    try {  
        ...  
        invoke method3;  
        statement5;  
    }  
    catch (Exception3 ex3) {  
        Process ex3;  
    }  
    statement6;  
}
```

An exception
is thrown in
method3

Call Stack

Catch or Declare Checked Exceptions

Suppose p2 is defined as follows:

```
void p2() throws IOException {  
    if (a file does not exist) {  
        throw new IOException("File does not exist");  
    }  
  
    ...  
}
```

Catch or Declare Checked Exceptions

Java forces you to deal with checked exceptions. If a method declares a checked exception (i.e., an exception other than Error or RuntimeException), you must invoke it in a try-catch block or declare to throw the exception in the calling method. For example, suppose that method p1 invokes method p2 and p2 may throw a checked exception (e.g., IOException), you have to write the code as shown in (a) or (b).

```
void p1() {  
    try {  
        p2();  
    }  
    catch (IOException ex) {  
        ...  
    }  
}
```

(a)

```
void p1() throws IOException {  
    p2();  
}
```

(b)

Example: Declaring, Throwing, and Catching Exceptions

- ♦ Objective: This example demonstrates declaring, throwing, and catching exceptions by modifying the setRadius method in the Circle class defined in Chapter 9. The new setRadius method throws an exception if radius is negative.

CircleWithException

TestCircleWithException

Rethrowing Exceptions

```
try {  
    statements;  
}  
catch (TheException ex) {  
    perform operations before exits;  
    throw ex;  
}
```

The `finally` Clause

```
try {  
    statements;  
}  
catch (TheException ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

Trace a Program Execution

Suppose no exceptions in the statements

```
try {  
    statements;  
}  
catch (TheException ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

Next statement;

Trace a Program Execution

```
try {  
    statements;  
}  
catch (TheException ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

The final block is
always executed

Next statement;

Trace a Program Execution

```
try {  
    statements;  
}  
catch (TheException ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

Next statement;

Next statement in
the method is
executed

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

Next statement;

Suppose an exception of type Exception1 is thrown in statement2

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

The exception is handled.

Next statement;

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}  
  
Next statement;
```

The final block is
always executed.

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
finally {  
    finalStatements;  
}
```

Next statement;

The next statement in the method is now executed.

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
catch (Exception2 ex) {  
    handling ex;  
    throw ex;  
}  
finally {  
    finalStatements;  
}
```

statement2 throws an exception of type Exception2.

Next statement;

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
catch (Exception2 ex) {  
    handling ex;  
    throw ex;  
}  
finally {  
    finalStatements;  
}
```

Handling exception

Next statement;

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
catch (Exception2 ex) {  
    handling ex;  
    throw ex;  
}  
finally {  
    finalStatements;  
}
```

Execute the final block

Next statement;

Trace a Program Execution

```
try {  
    statement1;  
    statement2;  
    statement3;  
}  
catch (Exception1 ex) {  
    handling ex;  
}  
catch (Exception2 ex) {  
    handling ex;  
    throw ex;  
}  
finally {  
    finalStatements;  
}
```

Next statement;

Rethrow the exception
and control is
transferred to the caller

Cautions When Using Exceptions

- ✦ Exception handling separates error-handling code from normal programming tasks, thus making programs easier to read and to modify. Be aware, however, that exception handling usually requires more time and resources because it requires instantiating a new exception object, rolling back the call stack, and propagating the errors to the calling methods.

When to Throw Exceptions

- An exception occurs in a method. If you want the exception to be processed by its caller, you should create an exception object and throw it. If you can handle the exception in the method where it occurs, there is no need to throw it.

When to Use Exceptions

When should you use the try-catch block in the code? You should use it to deal with unexpected error conditions. Do not use it to deal with simple, expected situations. For example, the following code

```
try {  
    System.out.println(refVar.toString());  
}  
  
catch (NullPointerException ex) {  
    System.out.println("refVar is null");  
}
```

When to Use Exceptions

is better to be replaced by

```
if (refVar != null)
```

```
    System.out.println(refVar.toString());
```

```
else
```

```
    System.out.println("refVar is null");
```

Defining Custom Exception Classes

- ✦ Use the exception classes in the API whenever possible.
- ▢ Define custom exception classes if the predefined classes are not sufficient.
- ▢ Define custom exception classes by extending `Exception` or a subclass of `Exception`.

Custom Exception Class Example

In Listing 13.8, the setRadius method throws an exception if the radius is negative. Suppose you wish to pass the radius to the handler, you have to create a custom exception class.

InvalidRadiusException

CircleWithRadiusException

TestCircleWithRadiusException

Assertions

An assertion is a Java statement that enables you to assert an assumption about your program. An assertion contains a Boolean expression that should be true during program execution. Assertions can be used to assure program correctness and avoid logic errors.

Declaring Assertions

An *assertion* is declared using the new Java keyword assert in JDK 1.4 as follows:

assert assertion; or
assert assertion : detailMessage;

where **assertion** is a Boolean expression and *detailMessage* is a primitive-type or an Object value.

Executing Assertions

When an assertion statement is executed, Java evaluates the assertion. If it is false, an `AssertionError` will be thrown. The `AssertionError` class has a no-arg constructor and seven overloaded single-argument constructors of type `int`, `long`, `float`, `double`, `boolean`, `char`, and `Object`.

For the first assert statement with no detail message, the no-arg constructor of `AssertionError` is used. For the second assert statement with a detail message, an appropriate `AssertionError` constructor is used to match the data type of the message. Since `AssertionError` is a subclass of `Error`, when an assertion becomes false, the program displays a message on the console and exits.

Executing Assertions Example

```
public class AssertionDemo {  
    public static void main(String[] args) {  
        int i; int sum = 0;  
        for (i = 0; i < 10; i++) {  
            sum += i;  
        }  
        assert i == 10;  
        assert sum > 10 && sum < 5 * 10 : "sum is " + sum;  
    }  
}
```

Compiling Programs with Assertions

Since assert is a new Java keyword introduced in JDK 1.4, you have to compile the program using a JDK 1.4 compiler. Furthermore, you need to include the switch `–source 1.4` in the compiler command as follows:

```
javac –source 1.4 AssertionDemo.java
```

NOTE: If you use JDK 1.5, there is no need to use the `–source 1.4` option in the command.

Running Programs with Assertions

By default, the assertions are disabled at runtime. To enable it, use the switch `—enableassertions`, or `—ea` for short, as follows:

```
java —ea AssertionDemo
```

Assertions can be selectively enabled or disabled at class level or package level. The disable switch is `—disableassertions` or `—da` for short. For example, the following command enables assertions in package package1 and disables assertions in class Class1.

```
java —ea:package1 —da:Class1 AssertionDemo
```

Using Exception Handling or Assertions

Assertion should not be used to replace exception handling. Exception handling deals with unusual circumstances during program execution. Assertions are to assure the correctness of the program. Exception handling addresses robustness and assertion addresses correctness. Like exception handling, assertions are not used for normal tests, but for internal consistency and validity checks. Assertions are checked at runtime and can be turned on or off at startup time.

Using Exception Handling or Assertions, cont.

Do not use assertions for argument checking in public methods. Valid arguments that may be passed to a public method are considered to be part of the method's contract. The contract must always be obeyed whether assertions are enabled or disabled. For example, the following code in the Circle class should be rewritten using exception handling.

```
public void setRadius(double newRadius) {  
    assert newRadius >= 0;  
    radius = newRadius;  
}
```

Using Exception Handling or Assertions, cont.

Use assertions to reaffirm assumptions. This gives you more confidence to assure correctness of the program. A common use of assertions is to replace assumptions with assertions in the code.

Using Exception Handling or Assertions, cont.

Another good use of assertions is place assertions in a switch statement without a default case. For example,

```
switch (month) {  
    case 1: ... ; break;  
    case 2: ... ; break;  
    ...  
    case 12: ... ; break;  
    default: assert false : "Invalid month: " + month  
}
```

The File Class

The File class is intended to provide an abstraction that deals with most of the machine-dependent complexities of files and path names in a machine-independent fashion. The filename is a string. The File class is a wrapper class for the file name and its directory path.

Obtaining file properties and manipulating file

java.io.File	
+File(pathname: String)	Creates a <code>File</code> object for the specified path name. The path name may be a directory or a file.
+File(parent: String, child: String)	Creates a <code>File</code> object for the child under the directory parent. The child may be a file name or a subdirectory.
+File(parent: File, child: String)	Creates a <code>File</code> object for the child under the directory parent. The parent is a <code>File</code> object. In the preceding constructor, the parent is a string.
+exists(): boolean	Returns true if the file or the directory represented by the <code>File</code> object exists.
+canRead(): boolean	Returns true if the file represented by the <code>File</code> object exists and can be read.
+canWrite(): boolean	Returns true if the file represented by the <code>File</code> object exists and can be written.
+isDirectory(): boolean	Returns true if the <code>File</code> object represents a directory.
+isFile(): boolean	Returns true if the <code>File</code> object represents a file.
+isAbsolute(): boolean	Returns true if the <code>File</code> object is created using an absolute path name.
+isHidden(): boolean	Returns true if the file represented in the <code>File</code> object is hidden. The exact definition of <i>hidden</i> is system-dependent. On Windows, you can mark a file hidden in the File Properties dialog box. On Unix systems, a file is hidden if its name begins with a period(.) character.
+getAbsolutePath(): String	Returns the complete absolute file or directory name represented by the <code>File</code> object.
+getCanonicalPath(): String	Returns the same as <code>getAbsolutePath()</code> except that it removes redundant names, such as "." and "..", from the path name, resolves symbolic links (on Unix), and converts drive letters to standard uppercase (on Windows).
+getName(): String	Returns the last name of the complete directory and file name represented by the <code>File</code> object. For example, new <code>File("c:\\book\\test.dat").getName()</code> returns <code>test.dat</code> .
+getPath(): String	Returns the complete directory and file name represented by the <code>File</code> object. For example, new <code>File("c:\\book\\test.dat").getPath()</code> returns <code>c:\\book\\test.dat</code> .
+getParent(): String	Returns the complete parent directory of the current directory or the file represented by the <code>File</code> object. For example, new <code>File("c:\\book\\test.dat").getParent()</code> returns <code>c:\\book</code> .
+lastModified(): long	Returns the time that the file was last modified.
+length(): long	Returns the size of the file, or 0 if it does not exist or if it is a directory.
+listFile(): File[]	Returns the files under the directory for a directory <code>File</code> object.
+delete(): boolean	Deletes the file or directory represented by this <code>File</code> object. The method returns true if the deletion succeeds.
+renameTo(dest: File): boolean	Renames the file or directory represented by this <code>File</code> object to the specified name represented in <code>dest</code> . The method returns true if the operation succeeds.
+mkdir(): boolean	Creates a directory represented in this <code>File</code> object. Returns true if the the directory is created successfully.
+mkdirs(): boolean	Same as <code>mkdir()</code> except that it creates directory along with its parent directories if the parent directories do not exist.

Problem: Explore File Properties

Objective: Write a program that demonstrates how to create files in a platform-independent way and use the methods in the File class to obtain their properties. The following figures show a sample run of the program on Windows and on Unix.

```
Command Prompt
C:\book>java TestFileClass
Does it exist? true
Can it be read? true
Can it be written? true
Is it a directory? false
Is it a file? true
Is it absolute? false
Is it hidden? false
What is its absolute path? C:\book\image\us.gif
What is its canonical path? C:\book\image\us.gif
What is its name? us.gif
What is its path? image\us.gif
When was it last modified? Sat May 08 14:00:34 EDT 1999
What is the path separator? ;
What is the name separator? \

C:\book>
```

```
Command Prompt - telnet panda
$ pwd
/home/liang/book
$ java TestFileClass
Does it exist? true
Can it be read? true
Can it be written? true
Is it a directory? false
Is it a file? true
Is it absolute? false
Is it hidden? false
What is its absolute path? /home/liang/book/image/us.gif
What is its canonical path? /home/liang/book/image/us.gif
What is its name? us.gif
What is its path? image/us.gif
When was it last modified? Wed Jan 23 11:00:14 EST 2002
What is the path separator? /
What is the name separator? /

$
```

TestFileClass

Text I/O

A File object encapsulates the properties of a file or a path, but does not contain the methods for reading/writing data from/to a file. In order to perform I/O, you need to create objects using appropriate Java I/O classes. The objects contain the methods for reading/writing data from/to a file. This section introduces how to read/write strings and numeric values from/to a text file using the Scanner and PrintWriter classes.

Writing Data Using PrintWriter

java.io.PrintWriter

+PrintWriter(filename: String)

Creates a PrintWriter for the specified file.

+print(s: String): void

Writes a string.

+print(c: char): void

Writes a character.

+print(cArray: char[]): void

Writes an array of character.

+print(i: int): void

Writes an int value.

+print(l: long): void

Writes a long value.

+print(f: float): void

Writes a float value.

+print(d: double): void

Writes a double value.

+print(b: boolean): void

Writes a boolean value.

Also contains the overloaded
println methods.

A println method acts like a print method; additionally it prints a line separator. The line separator string is defined by the system. It is `\r\n` on Windows and `\n` on Unix. The printf method was introduced in §4.6, “Formatting Console Output and Strings.”

Also contains the overloaded
printf methods.

WriteData

Try-with-resources

Programmers often forget to close the file. JDK 7 provides the followings new try-with-resources syntax that automatically closes the files.

```
try (declare and create resources) {  
    Use the resource to process the file;  
}
```

WriteDataWithAutoClose

Reading Data Using Scanner

java.util.Scanner	
+Scanner(source: File)	Creates a Scanner object to read data from the specified file.
+Scanner(source: String)	Creates a Scanner object to read data from the specified string.
+close()	Closes this scanner.
+hasNext(): boolean	Returns true if this scanner has another token in its input.
+next(): String	Returns next token as a string.
+nextByte(): byte	Returns next token as a byte.
+nextShort(): short	Returns next token as a short.
+nextInt(): int	Returns next token as an int.
+nextLong(): long	Returns next token as a long.
+nextFloat(): float	Returns next token as a float.
+nextDouble(): double	Returns next token as a double.
+useDelimiter(pattern: String): Scanner	Sets this scanner's delimiting pattern.

ReadData

Problem: Replacing Text

Write a class named ReplaceText that replaces a string in a text file with a new string. The filename and strings are passed as command-line arguments as follows:

```
java ReplaceText sourceFile targetFile oldString newString
```

For example, invoking

```
java ReplaceText FormatString.java t.txt StringBuilder StringBuffer
```

replaces all the occurrences of StringBuilder by StringBuffer in FormatString.java and saves the new file in t.txt.

ReplaceText

Reading Data from the Web

Just like you can read data from a file on your computer, you can read data from a file on the Web.

Reading Data from the Web

```
URL url = new URL("www.google.com/index.html");
```

After a **URL** object is created, you can use the **openStream()** method defined in the **URL** class to open an input stream and use this stream to create a **Scanner** object as follows:

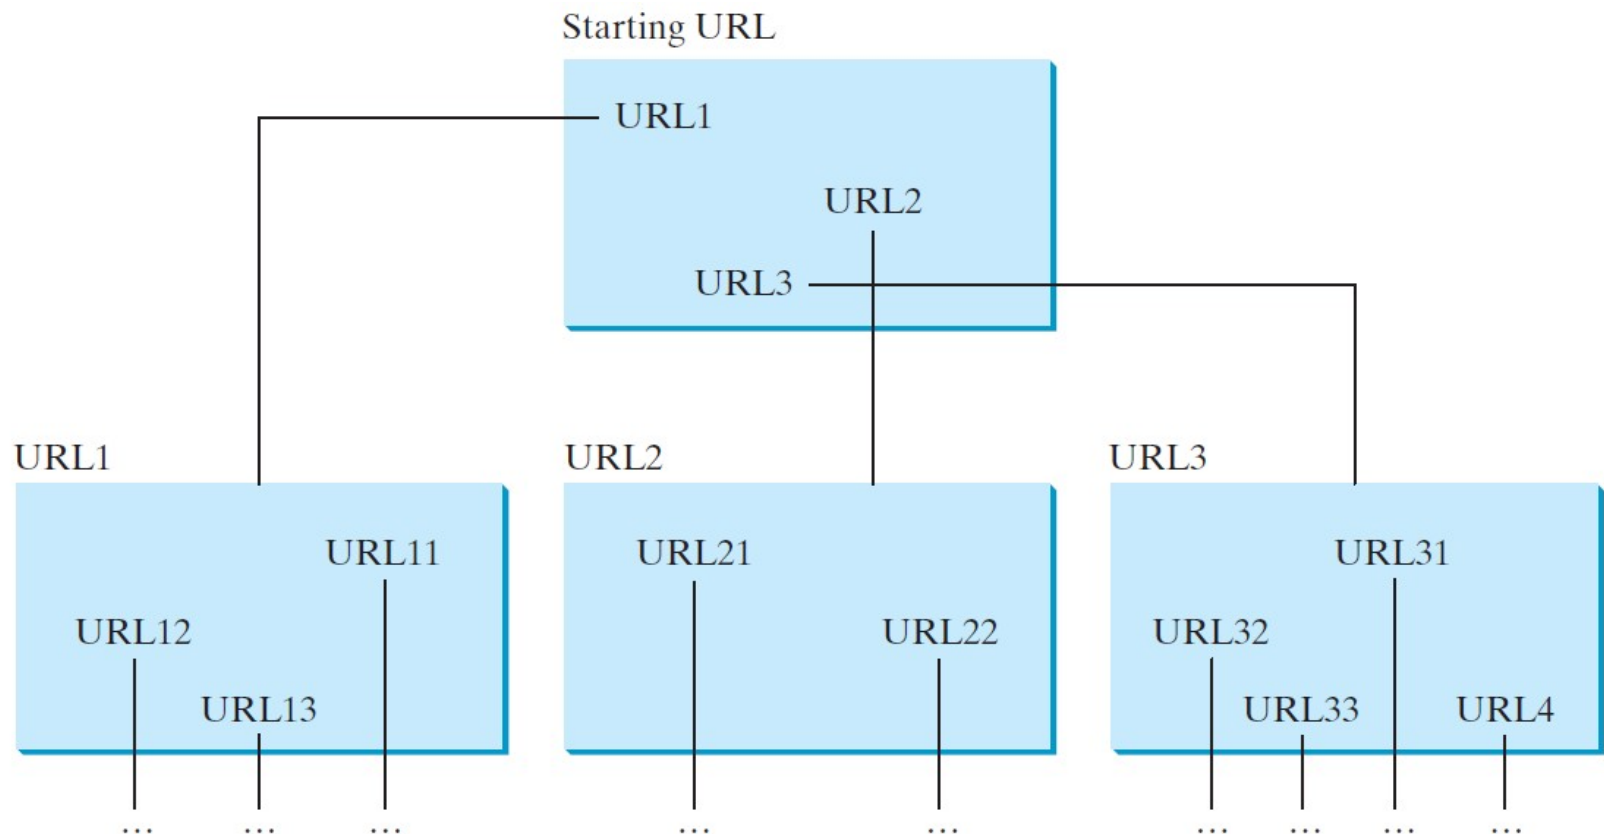

```
Scanner input = new Scanner(url.openStream());
```

ReadFileFromURL

Case Study: Web Crawler

This case study develops a program that travels the Web by following hyperlinks.

Case Study: Web Crawler

The program follows the URLs to traverse the Web. To avoid that each URL is traversed only once, the program maintains two lists of URLs. One list stores the URLs pending for traversing and the other stores the URLs that have already been traversed. The algorithm for this program can be described as follows:

Case Study: Web Crawler

```
Add the starting URL to a list named listOfPendingURLs;
while listOfPendingURLs is not empty {
    Remove a URL from listOfPendingURLs;
    if this URL is not in listOfTraversedURLs {
        Add it to listOfTraversedURLs;
        Display this URL;
        Exit the while loop when the size of S is equal to 100.
        Read the page from this URL and for each URL contained in
the page {
        Add it to listOfPendingURLs if it is not is listOfTraversedURLs;
    }
}
}
```

WebCrawler
